

THE ONESQUETHAW-COEYMAN'S WATERSHED STUDY

Prepared by:

**Onesquethaw-Coeymans Watershed Council
and
Capital District Regional Planning Commission**

May 2008

Special Thanks to the following for their input:

Joseph Arabski	City of Albany Water Department
Jim Boyle	Clearwater Chapter Trout Unlimited
Laura DeGaetano	Albany County Water Quality Coordinating Committee
Tom Della Rocco	USDA Farm Service Agency
Dan Driscoll	Mohawk Hudson Land Conservancy
Todd Fabozzi	Capital District Regional Planning Commission
Tom Gallagher	Cornell Cooperative Extension, Albany County
Roy Lambertson	Clearwater Chapter Trout Unlimited & Project Coordinator
Sylvia Lawler	Watershed Citizen
Fred Realbuto	Audubon Society of New York State
Joseph Slezak	Albany County Soil & Water Conservation District
Numerous Staff Members	NYS Dept of Environmental Conservation, Region 4, Central Office, and Hudson River Estuary Program

New York State Department of Environmental Conservation
provided funding for this project from the Environmental Protection Fund
through the Hudson River Estuary Program.

10.10. Where the Coeymans Meets the Hudson.....	172
10.11. List of Charts and Graphs.....	175

1 – Executive Summary

The Onesquethaw-Coeymans (OC) watershed is located in southeastern Albany County, New York. The watershed encompasses an area of approximately fifty-two square miles, which includes portions of five municipalities - the towns of Berne, New Scotland, Bethlehem, and Coeymans, and the village of Ravena. From its headwaters in the Helderbergs west of Clarksville, the stream travels approximately 19 miles in its 1400-foot descent to the Hudson River. It enters the Hudson just east of the village of Ravena about 12 miles south of the city of Albany.

The Onesquethaw Coeymans Watershed Council (OCWC) was incorporated in 2000 as a not-for-profit organization. The founding organizations are Trout Unlimited, Audubon Society of New York, the Albany County Water Quality Coordinating Committee and the Mohawk Hudson Land Conservancy.

The purpose of the OCWC is to protect and improve the quality of the creek and its watershed for the benefit of people, wildlife and the environment. This watershed assessment, funded by a grant from DEC's Hudson River Estuary Program, is a major step in achieving that purpose; it provides the foundation for a comprehensive watershed management plan.

Section 3, entitled A Brief Watershed Tour, gives an overview of important points along the creek, highlighting problems that must be addressed. For example, at the confluence of the Onesquethaw and Coeymans, the clear water of the Onesquethaw joins the murky water of the Coeymans. Just below the confluence, eroding banks and debris jams make the creek's shorelines unstable, contributing sediment that impacts water quality. The obvious questions are "why" and "what can and should be done about it?"

Section 4, Watershed Concept Descriptions, provides the general background readers need to understand the report. Included is a description of a watershed; a discussion of the various parts of a watershed, such as stream banks, riparian zone, and flood planes; an explanation of how streams evolve; and how various man-made features of a watershed, such as impervious surfaces, can influence that evolution.

Section 5 shows the location and explains the relevance of specific features within the Onesquethaw Coeymans Watershed, including wetlands, flood plains, steep slopes and water bodies. One particularly important feature is the limestone bedrock in much of the Onesquethaw

watershed; during periods of low-flow, sections of the creek disappear and flow underground through crevasses, caves and other conduits in the limestone. One result is that the creek is cooled when it flows through the bedrock, helping to provide excellent trout habitat. On the other hand, in areas where the limestone is close to the surface, any polluted surface water can easily enter those same crevasses and flow long distances, unfiltered by soil, to pollute the stream.

Section 6, Human Impacts Within the Watershed, describes the diverse range of land uses within the watershed, and describes the ways those land uses interact with the watershed.

This section also describes point source pollution (such as discharges from pipes), which are regulated by the state; and non-point source pollution, which is of diffuse origin, such as street pavement, atmospheric fallout and agriculture. According to DEC, nonpoint sources are the primary sources of contamination for more than 90% of the impaired waterbodies in the state.

Section 6 goes on to describe water and sewer systems within the watershed, water diversions (such as the diversion to Vly Reservoir), landfills, mining, dams and agriculture. The section also mentions trout stocking; while indiscriminate stocking of hatchery fish can reduce healthy wild trout populations, this is not the case in this stream.

Section 7 describes monitoring and other observations done in the watershed. This includes: fisheries, water quality and biomonitoring done by DEC and graduate students, stream flow monitoring done by US Geological Survey, and temperature monitoring done by Trout Unlimited. The section also describes some stream stability work done by the Albany County Soil and Water Conservation District, and various observations of watershed biodiversity (such as work done as part of a Hudsonia biodiversity training program organized by OCWC).

Section 8, Law and Regulation Related to the Watershed, summarizes federal, state, county and local regulations that control activities in the watershed. Federal controls include the National Environmental Policy Act, the Clean Water Act, and various federal mandates for agriculture. State controls include the State Environmental Quality Review Act (SEQRA), State Pollution Discharge Elimination System (SPDES) permits, the Freshwater Wetlands Act, and other provisions of Conservation Law. The state and county health departments control residential wastewater treatment systems.

Local laws regulating land use and site design, as well as regulations pertaining to soil erosion, sedimentation and storm water runoff are found in zoning ordinances, subdivision laws,

site plan regulations, or in stand-alone laws. Just as there is a wide variation in the development pressures facing each municipality in the watershed, there is a broad range in the way the communities regulate land use, site design, and the impacts of erosion, sedimentation and storm water runoff. A table summarizes the controls, and relevant excerpts are included in an appendix.

Section 9, Issues and Conclusions, includes a series of recommendations for implementation at the municipal level. All of the communities within the watershed fall short of the impervious surface standards recommended by the Center for Watershed Protection. Large lots, large setbacks, overly wide roads, and oversized parking lots are required by local regulations, creating the potential for unnecessary, excessive impervious surfaces. Across the country many communities are starting to recognize that the suburban zoning and subdivision regulations that have become standard over the last half-century are in need of revision because they essentially mandate sprawl-type growth (while making smart growth illegal).

Smart growth means encouraging development at higher densities in key areas and limiting it in others. Smart growth is growth that is compact, connected, diverse (mixed-uses) and designed for both autos and non-auto mobility. A central recommendation is that municipalities modify their comprehensive plans, zoning laws, and subdivision regulations to efficiently facilitate this type of development.

Other recommendations for municipalities include: protect sensitive environmental areas; establish stream and wetland buffers; control construction related runoff; and conduct outreach, encouraging residents to adopt practices that reduce pollution.

Finally, there is a series of recommendations related to land fills, industrial activity (point discharges), barriers and water diversions, impervious surfaces, stream stability, public access to the stream, riparian buffers, land conservation and agriculture. For example, the stream corridor contains beautiful natural features such as waterfalls, caves, and gorges, which should be both protected and made accessible for public use. The stream itself contains a healthy population of wild trout, which could be a significant recreational resource for the residents of the region. Community organizations, local municipalities, and agencies should be alert to opportunities to obtain land and easements for public benefit.

The recommendations and implementation strategies developed by the OCWC and CDRPC, and presented in the Issues and Conclusions section of this watershed assessment

report, should be considered preliminary. As a next step, the OCWC will present this report to municipalities and other stakeholders for their comments, and the recommendations will be modified based on that input. The resulting Onesquethaw-Coeymans Watershed Management Plan is meant to serve as a guide to help the council, residents, and municipalities work together to promote the protection and improvement of water quality and stewardship of the watershed.
